

Build a Chatbot with Amazon Lex

Inder preet

Introducing Today's Project!

What is Amazon Lex?

Amazon Lex is an AWS service that helps you build a chatbot from scratch or pick up a generative- AI chatbot

How I used Amazon Lex in this project

we used Amazon Lex to create a bisc chatbot

One thing I didn't expect in this project was...

Well there were some difficult challenges like the concept of fallback intent which was easily covered in the documentation

This project took me...

it took me about 30 minutes to wrap up this part.

Setting up a Lex chatbot

I created my chatbot from scratch with Amazon Lex. Setting it up took me a couple of minutes.

While creating my chatbot, I also created a role with basic permissions because so that the bot is restricted towards only the intended data

In terms of the intent classification confidence score, I kept the default value of 0.40. This means how certain do you want the bot to be before responding

Intents

Intents are what the users are trying to achieve when they chat with a chatbot

I created my first intent, WelcomeIntent, to have a friendly conversation starter with the user.

The screenshot shows the 'Add language to bot' configuration window in the IBM Watson Assistant console. The window is titled 'Add language to bot' and has a 'help' link. It is set for 'Language: English (US)'. The configuration includes a 'Select language' dropdown menu with 'English (US)' selected. Below this is a 'Description - optional' text area. A note indicates 'Maximum 200 characters'. The 'Voice interaction' section has a dropdown menu with 'Ruth' selected. Below this is a 'Voice sample' section with a text input containing 'Hello, my name is Ruth. Let me know how I can assist you.' and a 'Play' button. At the bottom, there is an 'Intent classification confidence score threshold' section with a value of '0.40' and a note 'Min: 0.00, max: 1.00'. The window has 'Cancel', 'Add another language', and 'Save' buttons at the bottom right.

FallbackIntent

'I launched and tested my chatbot, which could respond successfully if I enter Hi,Hello,I need help,Can you help me?

My chatbot returned the error message 'Intent FallbackIntent is fulfilled' when I entered... This error message occurred because intent fallback is set at 0.40 and the bot is not completely trained.

The screenshot shows the AWS Lex console interface for adding a new language to an existing bot. The main heading is 'Add language to bot'. Under the 'Language: English (US)' section, there are several fields: 'Select language' (a dropdown menu showing 'English (US)'), 'Description - optional' (a text input field), 'Voice interaction' (a dropdown menu showing 'Bytts'), 'Voice sample' (a text input field with the example text 'Hello, my name is Ruth. Let me know how I can assist you.' and a 'Play' button), and 'Intent classification confidence score threshold' (a text input field showing '0.40' with a note 'Min: 0.00, max: 1.00'). At the bottom, there are three buttons: 'Cancel', 'Add another language', and 'Done'.

Configuring FallbackIntent

If your chatbot has a confidence score below 40% for all the intents you've defined (in our case, it's just the WelcomeIntent for now), the FallbackIntent is triggered.

To give the chatbot a more user friendly response to the user.

Variations

To configure FallbackIntent, I clicked on the fallback intent tab and made changes

I also added variations! What this means for an end user is that the user won't get the same message repeatedly when their question is not understood by the chatbot.
