

Save User Info with your Chatbot

Inder preet

Introducing Today's Project!

What is Amazon Lex?

Amazon Lex is a service for building chatbots with voice and text. It integrates with AWS services, enabling intelligent interactions, natural language understanding, and seamless automation for customer support.

How I used Amazon Lex in this project

We used Amazon Lex with Lambda to create a conversational bot which returns a user's bank balances and also replies to follow up questions

One thing I didn't expect in this project was...

The easy upgrades that are available in the AWS console

This project took me...

This project took me about an hour from scratch

Context Tags

Context tags in Amazon Lex store and check information across conversations. Output tags remember details for later use, while input tags verify if specific info is available before activating an intent, preventing repetitive questions.

The two types of context tags in Amazon Lex are: Output context tag: Remembers details after an intent is finished for later use. Input context tag: Checks if specific details are available before an intent activates, avoiding repetitive questions.

I created a context tag called ContextCheckBalance This context tag was created in the intent Check Balance This tag stores information about the Date of Birth of the user upto 5 tries or until 90 seconds

Add new context tag [X]

Context tag name

Expires after
 turns, or seconds

FollowUpCheckBalance

I created a new intent called FollowupCheckBalance. The purpose of this intent is to answer the follow up questions of a user in regards to the balance of the other accounts

This intent is connected to the previous intent I made, CheckBalance, because once the user shared their date of birth the information is stored upto 90 seconds and the user can ask a follow up question without sharing the details again

How about my `[accountType]` account?

What about `[accountType]` ?

And in `[accountType]` ?

Input Context Tag

I created an input context, contextCheckBalance, that pulls the previously saved information on Date of Birth and uses it for the upcoming conversation

▼ Default values - *optional*

#contextCheckBalance.dateOfBirth

Provide a default value, #value for a context value, or [variable] for session variable.

San Diego, #ContextTag.SlotName, [SessionAttributeName]

Add default value

The final result!

To see the context tags and followup intent in action, I asked my bot about the balance on the other account

If I had gone straight to trying to trigger FollowUpCheckBalance without setting up any context the function would have failed and would have asked the user their date of birth to create a context
